

FISHERIES MANAGEMENT PLAN

for

Mountain Lakes in the Clarks Fork of Yellowstone River Drainage

Montana

Patrick E. Marcuson (1980)
Michiel D. Poore (1991)
Department of Fish, Wildlife and Parks

Introduction

Absaroka-Beartooth Wilderness Lakes

The Absaroka-Beartooth Wilderness Area (A-B) established in 1978 encompasses 930,584 acres and contains more area over 10,000 feet in elevation than any other area in the U.S. It rates as one of the top four or five wilderness areas in the country, receiving about 320,000 visitor-days of use each year. For comparison, the Bob Marshall Wilderness area receives about 150,000 visitor-days use yearly. The Absarokee Beartooth Wilderness Area and lands immediately adjacent contain 948 high mountain lakes, 318 of which contain fish and 630 that are barren. Approximately 204 of these lakes have self-sustaining fisheries and 114 are stocked. Stocking schedules vary from early in some of the more heavily used areas to once every six to ten years in the lakes managed for trophy fisheries.

Pat Marcuson, during the time he worked for the Montana Department of Fish, Wildlife and Parks (MDFWP) out of Red Lodge, gathered a tremendous amount of information on the A-B lakes and created a massive data base. In 1980 he developed fisheries management plans for each major drainage. Since that time, a computer data base containing the latest information on the lakes with fisheries has also been developed. This data base is located at the MDFWP Regional Headquarters in Billings. Additional information about individual lakes can be obtained from that office.

The purpose of this document is to update the 1980 lake management plan with the latest fisheries information available for the mountain lakes in the Clarks Fork of Yellowstone River Drainage.

Methods

Mountain lake information is collected primarily by a lake survey team consisting of two temporary employees who spend about eight weeks backpacking into the remote lakes of the A-B mountains. Lakes scheduled for sampling are selected based on length of time since last survey, questions about the status of fish introductions, impending scheduled fish plants, and angler reports. Fish populations are monitored with lightweight experimental nylon gill nets, hook and line, and visual surveys. Additional information gathered includes lake access, pH, air and surface water temperatures, availability of firewood and campsites, and extent of recreation use. Observations are also made of aquatic invertebrates, cruising and rising fish, fish fry, and suitability of substrate for spawning. Inlet and outlet streams are visually surveyed for fish and spawning activity or potential.

Fish collected are weighted and measured, and scales are taken for later age determination. Live fish are released, dead fish are dissected to check for parasites and general health and condition; stomachs are examined for food organisms.

Spot creel checks are conducted by enforcement and fisheries personnel to determine catch rates and angler satisfaction with regulations. Additional angler use information was gathered during 1988 and 1989 with a voluntary trailhead creel information survey implemented at the major access points to the A-B wilderness area. The purpose of this survey was to address a proposed new three-fish limit, estimate harvest and catch rates, solicit public comments, and gather additional fisheries information. Supplemental fisheries information is also obtained from guides and outfitters, Wilderness Rangers and other Forest Service personnel, as well as reports from other Wilderness users.

Information gathered from all sources is summarized and analyzed to make fish management decisions for the mountain lakes. Regulations are adjusted as necessary to help achieve desired fish population levels. Stocking rates and individual lake management strategies are adjusted as necessary to maintain desired angler catch rates, fish growth rates, and species distribution. Summarized information is used to update the computer data base for each mountain lake sampled.

DESCRIPTION

Location and numbers of lakes

The Clarks Fork of the Yellowstone River originates in the high country of Montana as a maze of subdrainage streams. The river flows into Wyoming for some 60 stream miles before returning to Montana. The Clarks Fork drains 1,237 square miles of Park County, Wyoming (Kent and Pechacek 1972).

The Montana portion of the Clarks Fork River drainage (Figure 1) drains 117.2 square miles of the south side of the Beartooth Mountain Range. The area is administered by the Gardiner Ranger District of the Gallatin National Forest. A scattering of mineral claims and deeded property is included within the southwest portion of the unit. Cooke City, Montana is the nearest town to the drainage.

The Gallatin National Forest portion of the drainage has 424 mountain lakes. Only Jackson's Pond (#2) is on private property. The majority, 286 lakes, are in Carbon County; Park County has 132; Fox Lake is shared by both Carbon and Park Counties; and five lakes are interstate waters on the Montana-Wyoming border. Except for Line Lake and 13 lakes near Cooke City, all the lakes are within the Absaroka-Beartooth Wilderness Area. Line Lake (#426) occupies a 24.5 square mile drainage in the Beartooth Ranger District of the Custer National Forest in Carbon County, Montana near the Wyoming State Line.

Lake areas and depths

The Gallatin portion of the drainage has 4,273.6 acres of lake water, making 5.7% of this real estate under water. Lakes range from 0.4 acres to 291.8 acres with a 10-acre average for 425 lakes. The largest lake is Upper Aero at 291.8 acres, followed by Granite - 228.0 acres, Lower Aero - 189.9, and six other lakes that exceed 100 acres (Table 1). The total area of the 13 lakes outside the Absaroka-Beartooth Wilderness Area is 95.6 acres. Line Lake, in the Custer National Forest portion, is 4.7 acres with a maximum depth of 26 feet (Bishop 1967).

¹ See Figure 1 for locations.

² 10 = Carbon County; 49 = Park County; P = Park County, Wyoming.

³ C = Custer National Forest; G = Gallatin National Forest; S = Shoshone National Forest; P = Private.

⁴ 1 = Transition; 2 = Canadian; 3 = Subalpine; 4 = Alpine.

⁵ RB = Rainbow trout; CT'Y = Yellowstone Cutthroat trout; CT'M = McBride cutthroat trout; EB = Brook trout; H₂ = CTxGT (cutthroat x golden); LT = Lake trout; B = Barren of fish.

⁶ 1 = Self-sustaining; 2 = Stocked; 2a = Stocked but may become self-sustaining;

3 = Self-sustaining and stocked; 4 = Drifted in from upstream source.

⁷ 1 = No immediate management necessary; 2 = Stock at intervals; 3 = No fisheries potential;

4 = Rehabilitate and stock new species; 5 = Stock new species after present fisheries die out;

6 = Stock to establish self-sustaining population; 7 = Inhabit from upstream source.

⁸ One lake has potential, the other six have none.

⁹ Four lakes have brookies, three have no potential.

¹⁰ One lake has potential, three have none.

¹¹ One lake is barren and has no potential (B-3).

¹² Cutthroat trout from Jasper Lake.

The deepest lake in the drainage is Upper Aero at 195 feet (Marcuson 1974). Lakes steeper than 100 feet follow:

<u>Lake Number</u>	<u>Name</u>	<u>Maximum Depth</u>
31	Upper Aero	195
100	Lake of the Winds	186
29	Lower Aero	185
103	Otter	177
168	Lake Elaine	156
245	Albino	149
104	Rock Tree	130

121	Jorden	120
73	Rock Island	110
72	Widewater	110
36	Rough	110
237	Jasper	107

There are 33 lakes between 50-100 feet, 186 between 10 and 50 feet, and 186 less than 10 feet deep (Marcuson 1970, 1971, 1974, 1975, 1976). Six lakes were ice covered and no depths were measured.

Lake Elevations and Ecological Zones

The highest lake in the drainage is Unnamed #32 at 11,200 feet. In the same area near Granite Peak, is the uppermost Sky Top Lake at 11,100 feet. The lake at the lowest altitude in the drainage is Lower Vernon at 7,880 feet (Marcuson 1972). The 426 lakes in the Clarks Fork River drainage are distributed at the following elevations:

<u>Altitude in Feet</u>	<u>Number of Lakes</u>
7,000	4
8,000	27
9,000	213
10,000	170
11,000	12

Nine percent of the lakes are in the 9,000 to 10,000-foot range. Only four lakes above 10,500 feet have names. Sixty-one percent of the lakes occupy the Sub-alpine environment, 28% are in the Alpine Zone, and 11% are in the timbered habitat typical of the Canadian Zone.

Accessibility

U. S. Highway 212 between Red Lodge and Cooke City, Montana provides vehicle access to the area. Many four-wheel-drive trails, not designated as Forest roads, have been closed because of habitat destruction. The only roadways within the Montana portion are the Goose Lake jeep trail #3,230, Lulu Pass road #6,943 and Daisy Pass road #212. Other roads from highway 212 lead to trail heads in Wyoming which provide routes to waters in Montana. These include Lily Lake - Crazy Lake jeep trail #130, Muddy Creek, Clay Butte and Island Lake spur roads.

The drainage has some good trails providing access to most of the lake regions. Most of the country above Timberline is easily traveled without trails. Many unmaintained trails traverse the drainage, few of which are on maps. Of the 426 lakes, 13 can be driven to by 4x4 vehicle, 275 can be reached by horse, 138 are restricted to foot traffic, 78 lakes have trails to their lake shores or reasonably close, and 348 lakes have no trails.

Water Chemistry

According to surveys during the 1970's, chemical attributes for 90 lakes (Table 2) had a mean hydrogen ion concentration of 6.4. Conductivities ranged from 7 to 82 mhos. The average silica content was 1.0 ppm, iron averaged .10 ppm, alkalinity averaged 21 ppm and total hardness was 9 ppm. Waters were usually clear except those green lakes at high elevations influenced by glacial milk. Most lake substrates were visible to depths of 18 feet on clear, sunny days. Secchi disks were visible to 26 feet in the majority of the lakes. High flows caused little turbidity.

Thermal

Surface water temperatures peak about the 31st of August for most years. Ice goes off lakes and wide waters east of Cooke City from mid-May to early June. The majority of the lakes are much later with some ice-free by August 1, and others near the divide to the north never becoming totally ice-free. Lakes in ecological zone 2, Canadian, generally have approximately 153 ice-free days, subalpine waters have 125, and alpine waters have about 106 ice-free days.

Plankton

Volume and numbers of plankton found in samples from 110 lakes in the drainage vary widely (Table 3). The presence of large zooplankton, *Diaptomus shoshone*, *Daphnia middendorffiana* and *D. pulex*, are especially important to lakes with fisheries and/or lakes with fisheries potential. These large forms were found in 44% of the 110 lakes.

Fisheries

At the time this report was written, 31% (132) of the 426 lakes had a fishery. If all stocking were ended and the existing hatchery fish aged out and died, the 426 lakes in the drainage would have the following:

<u>Number of lakes</u>	<u>Fisheries status</u>
1	Lake Trout, Brook Trout mixed
57	Brook Trout (EB)
2	Grayling (GR)
5	Cutthroat Trout (CT)
294	Fishless
4	Rainbow Trout (RB), EB, GR mixed
3	RBxCT hybrids (H ₂)
3	RB, EB mixed
1	CT, GT mixed
10	CT, EB mixed
2	CT, GR mixed
1	EB, CT, GR mixed

At present, another 30 lakes are periodically stocked with Cutthroat Trout (and one with Rainbow Trout) to maintain a fishery. Under a no-management option, it is assumed that the above fish distribution (9 lakes) would remain reasonably static; fish densities would, however, be expected to fluctuate. Mixed fisheries would ultimately favor Brook Trout dominance where they are present with possible elimination of those species in cohabitation.

The stocking history for those plants with records (Table 4) is quite incomplete. During the late 1930's, an account of the first stocking of Rainbow Trout by Paul Tarrant, Billings, Montana was described by Herman Hendrickson (Marcuson 1980). Brook Trout 2-5 inches in length were hauled from the state hatchery at Big Timber to the Billings Municipal Airport and flown to three remote lakes 2 miles east of Goose Lake and 1 mile southeast of Grasshopper Glacier. The position best describes Upper and Lower Aero lakes (Figure 3) and Rough Lake. A plant of 15,000 trout was made in 4 hours' flight time.

Brook Trout, some albinos, were stocked in the late 1930's along the Goose Lake jeep trail. These fish provided stock for many subsequent transplants made primarily by Tommy Garrison, Cooke City, Montana.

Numerous other plants of Brook Trout were made by ranchers, prospectors and members associated with the Red Lodge Rod and Gun Club. These Brook Trout were transplanted from the holding at Old Richel Lodge to lakes in Wyoming and Montana. Fish were hauled on horseback to several lakes in the Tiel-Green-Lake Elaine area of the Clarks Fork drainage.

² CT'M = McBride cutthroat trout.; CT'Y = Yellowstone cutthroat trout; GR = Arctic grayling; GT = Golden trout; LT = Lake trout; RB = Rainbow trout; EB = Brook trout

³ SS = Self-sustaining population.

The State of Montana, Department of Fish and Game started stocking lakes with their own airplane in the 1940's. Brook Trout were flown to Sodalite Lake in 1959, introducing the species to yet another area within the drainage.

From all the Brook Trout plants, fish were available for transplants, and connected waters were soon invaded by the species. Numerous waters were and still are the result of these early introductions of brookies.

Rainbow Trout were planted by the Department in several waters in the drainage. These fish are still evident in Fox, Widewater, Canyon and the other Crazy Lakes downstream. The species was also introduced in other lakes in 1959, but were wiped out after Brook Trout were introduced and out-competed the Rainbow Trout.

More recent plants include the introduction of Grayling in 1955 to Aquarius, Sky Top and Cliff lakes. Present distribution has shifted these species downstream from these sites (Marcuson 1974). Plants now are almost exclusively Cutthroat Trout (Table 4).

In addition to cutthroat plants, other introductions made since 1980 include Rainbow Trout into Gallery Lake and lake trout into Kersey Lake. Rainbow Trout from Gallery Lake have moved downstream into one unnamed lake and into Cradle Lake. Arctic Grayling were introduced into Little Washtub, Indian Knife, Swamp, Mosquito, Skeeter, Spaghetti and Wiedy lakes. Golden Trout were planted into Big Butte, Desolation, Picasso, Rock Tree and Upper and Lower Whitney lakes. The status of most of these introductions is unknown at this time, and all are scheduled to be surveyed.

Six lakes have or had Cutthroat Trout populations that are yet unexplained. No hatchery records explain their origin. Plants in Lake of the Clouds, Big Butte and Zimmer Lakes are assumed to be stocking errors from air plants.

During 1988 and 1989 (Poore & Frazer 1990), a voluntary trailhead creel information survey was implemented at the major access points to the Absaroka-Beartooth Wilderness Area (A-B). That study showed, in spite of liberal fish limits for the A-B mountains, anglers kept only 26% of their catch in 1988 and 27% in 1989. Anglers release three out of four fish they presently catch without being required to by restrictive regulations. By a four to one majority, those fishermen responding to the survey wanted to see the present liberal fish limits retained in the A-B.

A-B anglers kept 35% of the Brook Trout they caught, 24% of the Rainbows and 22% of Cutthroat. The average catch per hour for each fish species was; 0.94 for Cutthroat Trout, 0.72 for Rainbow Trout, and 1.27 for Brook Trout. Catch rates for 1988 and 1989 were identical with 2.6 fish per hour on lakes, 4.3 fish per hour on streams, and 2.4 fish per hour for people fishing both lakes and streams.

MANAGEMENT RECOMMENDATIONS FOR LAKES IN THE CLARKS FORK RIVER DRAINAGE

Brook Trout are by far the most numerous fish species in the 102 lakes with fish. No additional lakes are recommended for this prolific species. Ideally, the fishery of this drainage would be enhanced if brookies were replaced by other trout in some subdrainages. Practically, such an undertaking would be prohibitive and in many circumstances next to impossible. One lake, Companion #15, has however been recommended for extermination of Brook Trout and replacement with Grayling. The Brook Trout population has been reduced to only a few individuals and only a minimal amount of rotenone would be needed to completely eliminate the existing fishery.

Experimental applications of rotenone have reduced the stunted population of Brook Trout in Long Lake. The food base has made some recovery and fish growth was improved enough that it is receiving some renewed angling interest. By applying rotenone under the ice in March or April when the lake is low in dissolved oxygen, a small amount of this expensive chemical had a significant impact. This technique should be used periodically on certain waters containing severely stunted populations of fish.

Another alternative is the use of a predator to control overpopulation. Marcuson recommended Lake Trout (Salvelinus namaycush) for Kersey and other lakes to help control overpopulation of Brook Trout. Lake Trout were introduced into Kersey Lake in 1981 and appear to be helping to control Brook Trout numbers. The average size of the Brook Trout has also increased since the Lake Trout were planted. Based on the Kersey Lake success, Lake Trout are recommended for introduction into Sodalite and Mariane lakes. Both these waters have stunted Brook Trout populations and physical features similar to those of Kersey Lake. Otter Lake was removed from the planting recommendations because a 1990 survey determined the Brook Trout were an acceptable size and appeared healthy. These introductions of a piscivorous species should be monitored to evaluate effectiveness and potential for other lakes with stunted Brook Trout populations.

It is not to be implied that Brook Trout are wholly undesirable in Beartooth waters. First, little can be done to alter their overwhelming presence and second, they provide considerable angling opportunity and camp fare. It is regrettable that they were not confined to closed lake systems which would have provided ample opportunity to fish for this species.

At present, Grayling reside alone in eight lakes and in combination with other species of fish in thirteen lakes. Grayling occur in limited numbers in several other drainage areas of the Absaroka-Beartooth Study Area. The status of Grayling does not appear to be endangered, but efforts to find suitable habitat to disperse distribution is advisable (Marcuson 1974). The most

stable isolated populations of Grayling exist in Cliff and Lower Cliff lakes. The latter lake is only a pond environment and winterkills regularly, but is restocked by recruitment from Cliff Lake upstream.

Most lakes with Grayling have shown continued declines in number. One may be hard pressed to find a Grayling in the lower Broadwater system. Where Grayling were once the dominant fish in size and number in Fox and Widewater lakes, they now occupy a subdominant role.

Because of declining numbers of Grayling, availability of suitable habitat and special concern status, Grayling were stocked in the following lakes: Swamp, Wiedy, Mosquito (Figure 4), Little Washtub, Indian Knife, Skeeter, Spaghetti and Burnt Bacon lakes (Table 5). It is too soon to know if these lakes have developed self-sustaining populations of Grayling, but additional monitoring and plants are scheduled in all these lakes except Swamp and Wiedy, which were planted with Cutthroat Trout after the Grayling died out.

In fewer waters, but with fair population abundance in the Clarks Fork River drainage, are Rainbow Trout. In 1980, Gallery #96 (Figure 5) was stocked with this species to add some angling diversity and attraction to geographic areas not readily used by people. Gallery and Cradle, located downstream, are the sole lakes in the drainage containing only Rainbow Trout.

With the exception of the 1920's introductions of Brook Trout into the Clarks Fork drainage, the next fish species introduced was the Golden Trout. During the summer of 1938 an unknown number of Golden Trout fry were stocked in Jasper Lake. These fish were originally from Cottonwood Lakes in California, shipped via the National Fish Hatchery in Bozeman, Montana. These fish matured and subsequently invaded Golden Lake (hence, its name) and Hidden Lake downstream. A remnant population of goldens coexisting with Cutthroat Trout still occupies Hidden Lake. On September 26, 1956 a transplant of goldens from Sylvan Lake was stocked in Lake of the Winds. These fish provided a unique fishery in Lake of the Winds (Figure 5) until 1970 when they died out as 14-year-old fish.

A study of this species revealed that Golden Trout populations statewide in Montana and nearby states are very limited (Marcuson 1984). By legislative action in California, no Golden Trout eggs were to be shipped out of California after 1919 (McCloud 1943).

It was also learned that goldens were long-lived fish, that natural reproduction occurred in outlet streams, with gravels containing less than 1% of silt-sized materials along shoal areas under the influence of moving outlet water (Marcuson 1984). A search of suitable habitat for goldens in the Absaroka-Beartooths revealed a few vacant niches. The lakes with the most suitable

habitat in the study area appear to be in the Desolation to Jorden Lake chain of seven lakes (Figure 6). Another chain of lakes with potential for Golden Trout is the Cloverleaf Chain (Figure 7). Better areas exist in the Martin to Robin (Whitcomb Lake on new Forest Service map) (Figure 8) lake chain, but this ideal water is saturated with Brook Trout.

Golden Trout were planted into Desolation, Big Butte, Upper and Lower Whitney (all located in the Desolation to Jorden Lake chain) and Rock Tree lakes during 1982. Initial survival appeared good, but by 1990 no goldens were found in any of these lakes. Additional plants are scheduled for these lakes in 1991. Goldens introduced into Picasso Lake in 1984 are doing well and should be closely monitored. If the species fails in these lakes, they could be managed for Cutthroat Trout.

Because of the limited amount of suitable habitat available, high angler demand, and very limited distribution, Golden Trout are recommended for the Cloverleaf and Sky Top chains of lakes ((Table 6). Cloverleaf Lakes (#215, #216, and #223) were last planted with Cutthroat in 1975. It was recommended to allow them to age-out because of a heavy trematode infestation. Sky Top Lakes (#1, #2, and #3) were planted with Grayling in the 1950's, but the lakes are now barren. Goldens planted into both chains of lakes would be isolated from other fish species and would have the potential to establish self-sustaining populations. If the species fails in these waters, Sky Top Lakes should be allowed to revert back to barren status, and Cloverleaf Lakes should be managed for Cutthroat Trout.

The basic management fish in high country lakes is the Cutthroat Trout, because of its suitability, performance, endemic status, availability and size, when needed for aerial stocking recommendations for this species are presented in Table 6. Swamp, Wiedy and Marsh lakes are recommended for Cutthroat Trout because of poor success with Grayling plants in these lakes. Cutthroat Trout plants in this table will represent the fluctuating fisheries in the drainage. The plan is for fish to be at various states of growth if stocked in nearby waters.

Many lakes should be left in a fishless state as potential study areas, niches for future fisheries sites or areas undisturbed by outside influences (Marcuson 1976). Of the 294 lakes presently fishless, 52 have fisheries potential. If this plan was carried out, the drainage would have the following:

<u>Status</u>	<u>Number of Lakes</u>	<u>Percent</u>
Brook Trout (EB)	54	
Cutthroat Trout (CT)	31	
Rainbow Trout (RB)	2	
Grayling (GR)	8	32
Golden Trout (GT)	14	
Mixed Species ¹	27	
Barren	290	68

¹Includes: LT, EB - 3; RBxCT (H₂) - 3; RB, EB - 3; RB,EB, GR - 4; GT, CT - 1; CT, EB - 10; CT, GR - 3 (LT = Lake Trout).

Many stream fisheries exist in the Clarks Fork drainage, much more so than typical of the majority of the Absaroka-Beartooth Study Area. It is unlikely that any of these waters had any indigenous stocks. The gradient of the Clarks Fork River channel east of Sunlight Basin probably deterred any natural upstream movement of fish. Most of the streams have brookies. Rainbow Trout occupy Crazy and Lake creeks, and Grayling are found in Cliff Creek. Distribution of the species follows introductions into the lentic habitats.

Numbers of people using the drainage has been increasing steadily since the early 1970's. Associated with this increased traffic has been an increase in the number of anglers. Implementation of more restrictive regulations throughout the entire A-B Wilderness at this time is not warranted because: 1) Use is restricted by difficult access and the large number of lakes containing fisheries. Maintained trails lead to less than half the lakes with fish. 2) Many A-B lakes need more harvest because they contain overabundant populations of Brook Trout and (in some lakes) Yellowstone Cutthroat. 3) Unlike most wilderness lakes many A-B lakes are uniquely fertile and productive. Even with liberal limits, optimum harvest has not been reached. 4) Our trailhead creel survey indicates people are regulating their own harvest and prefer this to being required to follow unnecessarily stringent regulations.

Several areas along major trails (especially where horses are allowed) are showing signs of overuse and may require some type of special management. Most A-B wilderness users, however, are satisfied with present management and the resource is in excellent shape.
